Università di Padova

AA 2022/2023 - Stat Lect. 3

Poisson Process

- Let $\{N(t), t \ge 0\}$ be a Poisson process
- N(t) represents the number of events occurred at or prior to time t
- a Poisson process has the properties:
- stationarity: given two equal time intervals, Δt_1 and Δt_2 , the probability of n events in Δt_1 is equal to that in Δt_2
- independent increments: the probability of n events in [t, t + s] is independent of how many events have accurred earlier
- orderliness: the occurrence of two or more events in a small time is practically impossible.
- given t > 0, N(t) is the number of events occurred between 0 and t. N(t) is a Poisson random variable with parameter λt :

$$P(N(t) = n) = \frac{(\lambda t)^n e^{-\lambda t}}{n!}$$

 a Poisson process is stationary and possesses independent increments: at any time t the process probabilistically starts all over again

Poisson Process: example

Problem

- children are born at a Poisson rate of 5/day in a countryside hospital. What is the probability that:
- a) at least two babies are born in the next six hours?
- b) no babis are born in the next two days?

Solution

- N(t) is the number of babes born from 0 to time t
- we assume that {N(t), t ≥ 0} is a Poisson process: it is stationary, it has independent increments and the probability of simultaneous births is zero
- one day is a time unit $\rightarrow \lambda = E[N(1)] = 5$

$$P(N(t) = n) = \frac{(5t)^n e^{-5t}}{n!}$$

a) the probability of two babies in the next six hours, i.e. t = 6/24 = 1/4 is

$$P(N(1/4) \ge 2) = 1 - P(N(1/4) = 0) - P(N(1/4) = 1) = 0.36$$

b) the probability of no baby born during the next two days is

$$P(N(2) = 0) = \frac{(10)^0 e^{-10}}{0!} = 4.5 \cdot 10^{-5}$$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

The Exponential distribution

- Let $\{N(t), t \ge 0\}$ be a Poisson process
- N(t) represents the number of events occurred at or prior to time t
- If T_1 is the time arrival of the 1st event
- T_i represents the elapsed time between the events T_i and T_{i-1}
- the ordered set $\{T_1, T_2, ..., T_n\}$ is a sequence of inter-arrival times of the Poisson process
- setting

$$P(N(t) = n) = \frac{(\lambda t)^n}{n!} e^{-\lambda t}$$

• we can evaluate the probability distribution function of the random variables T_j :

$$P(T_1 > t) = P(N(t) = 0) = e^{-\lambda t}$$

$$P(T_1 \le t) = 1 - P(T_1 > t) = 1 - e^{-\lambda t}$$

- a Poisson process is stationary and possesses independent increments: at any time t the process probabilistically starts all over again
- \rightarrow the inter-arrival time of any two consecutive events has the same distribution as T_1

The Exponential distribution

the cumulative distribution is therefore

$$F(t) = \begin{cases} 1 - e^{-\lambda t} & t \ge 0 \\ 0 & t < 0 \end{cases}$$

and the probability density function is

$$f(t) = \frac{dF(t)}{dt} = \begin{cases} \lambda e^{-\lambda t} & t \ge 0\\ 0 & t < 0 \end{cases}$$

the expected value and variance are

$$E[x] = \frac{1}{\lambda}$$
 and $Var(x) = \frac{1}{\lambda^2}$

Examples

- the inter-arrival time between two customers in a shop
- the duration of my next telephone call
- the time between two accidents at an intersection
- time until the next baby is born in a hospital
- the time to failure of the next chip in a large group of such devices when all of them are initially

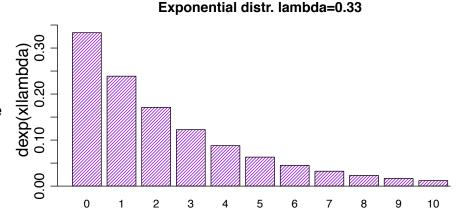

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Exponential distribution - exercise

Problem

- suppose that every three months, an earthquake of some entity happens in Italy
- what is the probability that the next earthquake happens after three but before seven months?

Solution

- X: the time, in months, until the next earthquake
- X is exponential with $\lambda = 1/3$

P(3<X<7) = 0.270907473307037

$$P(3 < X < 7) = F(7) - F(3) = (1 - e^{7/3}) - (1 - e^{3/3})$$

lambda $\leftarrow 1/3$; x $\leftarrow 0:10$; ap $\leftarrow dexp(x,lambda)$

barplot(ap, names=x, col='darkviolet', xlab='x', ylab='dexp(x|lambda)', density=30, main = sprintf("Exponential_distr._lambda=%.2f",lambda), ylim=c(0,0.375),cex.lab=1.5, cex.axis=1.25, cex.main=1.25, cex.sub=1.5)

 $cat(paste(c("P(3<X<7)_==", pexp(7,lambda) - pexp(3,lambda),'\n')))$

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

A. Garfagnini (UniPD)

a non-negative random variable X is memory-less if

$$P(X > s + t | X > t) = P(X > s)$$
 $\forall s, t \ge 0$

since

$$P(X > s + t, X > t) = P(X > s + t | X > t)P(X > t)$$

$$\frac{P(X>s+t,X>t)}{P(X>t)}=P(X>s)$$

and

$$P(X > s + t) = P(X > s) \cdot P(X > t)$$

since

$$P(X > s + t) = 1 - (1 - \exp(-\lambda(s + t))) = \exp(-\lambda(s + t)) = \exp(-\lambda s) \exp(-\lambda t)$$

and

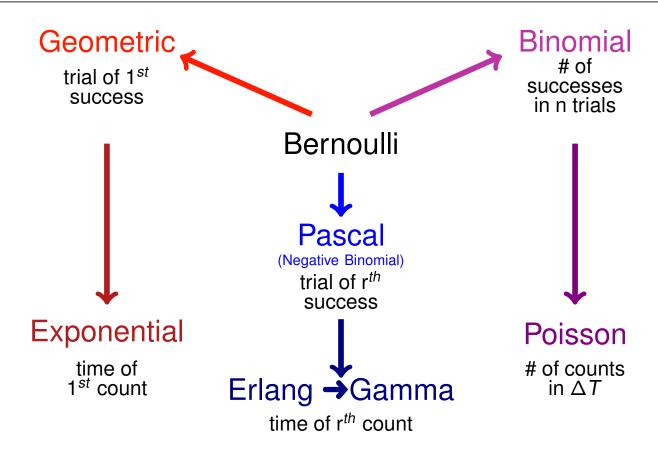

$$P(X > s) = 1 - (1 - \exp(-\lambda s)) = \exp(-\lambda s))$$

$$P(X > t) = 1 - (1 - \exp(-\lambda t)) = \exp(-\lambda t)$$

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Summary of discrete probability distributions

A. Garfagnini (UniPD)

Hypergeometric distribution

- suppose we have a box containing B black stones and N B white stones and we draw them, randomly, without replacement
- if the number of drawn items, n, does not exceed the number of black or white balls, i.e. $n \le min(B, N B)$
- and if X identifies the number of black stones extracted, its probability distribution follows the Hypergeometric distribution

$$P(x \mid N, B, n) = \frac{\binom{B}{x}\binom{N-B}{n-x}}{\binom{N}{n}}$$
 with $x = \{0, 1, 2, ..., n\}$

the expected value and variance are

$$E[x] = \frac{nB}{N}$$
 and $Var(x) = \frac{nB(N-B)}{N^2} \left(1 - \frac{n-1}{N-1}\right)$

 note that if sampling is done with replacement, X follows a binomial distribution with parameters n and B/N

$$E[x] = n \frac{B}{N}$$
 and $Var(x) = n \frac{B}{N} \left(1 - \frac{B}{N} \right)$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Standard Continuous Distributions

A. Garfagnini (UniPD)

The Uniform Distribution

 a random variable X ~ U(a, b) follows a uniform distribution if the pdf is given by the following:

$$f(X) = \begin{cases} \frac{1}{b-a} & a < x < b \\ 0 & otherwise \end{cases}$$

the cumulative density function is

$$F(X) = \begin{cases} 0 & x < a \\ \frac{x-a}{b-a} & a < x < b \\ 1 & x > b \end{cases}$$

• and the expected value and variance are

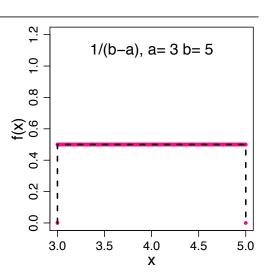

$$E[X] = \frac{a+b}{2}$$
 and $Var(x) = \frac{(b-a)^2}{12}$

A. Garfagnini (UniPD)

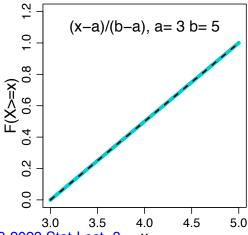

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

The Uniform distribution in R

- we have four pre-defined functions:
- dunif(x, min=0, max=1) returns the probability density function
- punif(q, min=0, max=1) gives the cumulative distribution function
- qunif(p, min=0, max=1) is the quantile returning function
- runif(n, min=0, max=1) generate a vector with random values from a uniform distribution
- if not specified, the default interval is (0, 1)

10

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Example: sum of two Uniform distributions

- let's suppose two random variables, x_1 and x_2 follow a uniform distribution, $x_i \sim \mathcal{U}(0, 1)$
- let's compute the $y = x_1 + x_2$ distribution function

$$f(y) = \begin{cases} y & 0 \le y \le 1 \\ 2 - y & 1 \le y \le 2 \\ 0 & \text{otherwise} \end{cases}$$

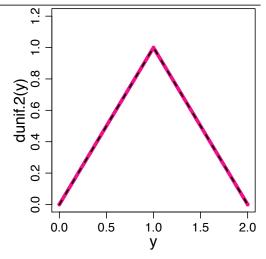

integrating f(y) in the domain we get

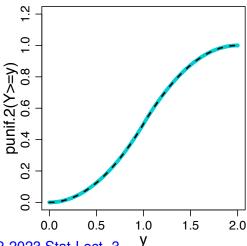

$$F(y) = \begin{cases} 0 & y < 0 \\ y^2/2 & 0 \le y \le 1 \\ -y^2/2 + 2y - 1 & 1 \le y \le 2 \\ 1 & y > 2 \end{cases}$$

the expected value and variance are

$$E[X] = \int_{0}^{1} yf(y)dy = 1$$
, $E[X^{2}] = \frac{7}{6}$

$$Var(x) = \int_{2}^{1} (y-1)^{2} f(y) dy = \frac{1}{6}$$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Example: sampling from a user's pdf

- all cumulative distributions are monotone increasing functions in the interval [0, 1]
- if the analytical form of F(X) is known, it is also invertible:

$$F^{-1}(y) = \inf\{x : F(x) \ge y\} \quad u \in [0,1]$$

- there is a 1:1 correspondence between CDFs, since they have the same image
- given X and Y with CDFs F(X) and G(Y)
- we ask for the same probability, and search for x_i and y_i such that

$$F(x_i) \equiv P(X \le x_i) = G(y_i) \equiv P(Y \le y_i)$$

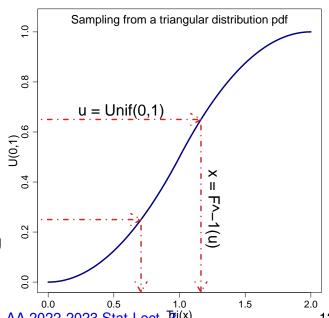

assuming

$$G(y) = \mathcal{U}(0,1) = u$$

$$\to F(x_i) = u$$

$$\to x_i = F^{-1}(u)$$

 this is called the inverse transform sampling method

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. Ti(x)

13

The Inverse Transform on the Triangular distribution

Algorithm

- 1) extract a sample from $\mathcal{U}(0,1)$
- 2) compute $F^{-1}(u) = x$
- 3) release x as sampled from our F(x)
- we define the new rinf.2() and qinf.2() functions

```
runif.2(3*10^3)

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Integrating a pdf with R

we have computed the mean and variance values, analytically

$$E[X] = \int_{0}^{1} y f(y) dy$$
 and $E[X^{2}] = \int_{0}^{1} y^{2} f(y) dy$

and now we ask R to do it for us

Evaluate the mean value and variance, by integration The mean value of the distribution is: 1 and the variance: 0.166666666666666666

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

The integrate() R function

• an adaptive quadrature of functions of one variable over a finite or infinite interval

```
integrate(f, lower, upper, ...)
```

• f() is an R function taking a numeric first argument and returning a numeric vector of the same length.

```
x.integral <- integrate(function(x) {x*dunif.2(x)}, lower=0, upper=2)</pre>

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Inequalities

- we will discuss three important inequalities:
- Markov's inequality
- Jensen's inequality
- Chebyshev's inequality
- they are very useful when we do not have enough information about the distribution of random variables
- but we can calculate their expected values and/or variances
- using the, bounds on probabilities can be derived

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

17

Markov's Inequality

- X is a non-negative random variable with $E[x] = \mu$
- for any k > 0

$$P(X \ge k) \le \frac{\mu}{k}$$

Proof

- let's do it for a discrete random variable X, with pdf p(x) over a set A
- let $B \subset A$, defined as $B = \{x \in A : x \ge k\}$

$$E[X] = \sum_{x \in A} x \ p(x) \ge \sum_{x \in B} x \ p(x)$$

$$\geq k \sum_{x \in B} p(x) = k P(X \geq k)$$

• in a similar way it can be demonstrated for continuous variables

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

18

Markov's Inequality application

Exercise

- a post office handles, on average, 10⁴ letters per day
- (a) what is the probability that, tomorrow, it will handle at least 1.5 104 letters?
- (b) and less than 1.5 104 letters?

Solution

- the average value of handled letters is $E[X] = 10^4$
- from Markov's inequality

$$P(X \ge 1.5 \ 10^4) \le \frac{E[X]}{1.5 \ 10^4} = \frac{2}{3}$$

• the second question is answered using the normalization of the probability

$$P(X < 1.5 \ 10^4) = 1 - P(X \ge 1.5 \ 10^4) = \frac{1}{3}$$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Jensen's Inequality

• the variance of a random variable is always a positive value

$$Var(X) = E[X^2] - (E[X])^2 \ge 0$$

• therefore the most basic moment inequality is

$$E[X^2] \ge (E[X])^2$$

Jensen's inequality

- let X be a random variable with finite mean $\mu = E[X]$
- let $g(x) : \mathbb{R} \longrightarrow \mathbb{R}$, a convex function (i.e. $d^2g/dx^2 > 0$)

$$g(E[X]) \leq E[g(X)]$$

Example

- X, positive random variable with $E[X] = \mu$, finite
- we consider $g(x) = x^{-1}$, x > 0
- g is convex, since $g'' = 2 \cdot x^{-3} > 0$, $\forall x > 0$
- from Jensen's inequality:

$$E\left[\frac{1}{x}\right] \ge \frac{1}{E[X]} \iff E\left[\frac{1}{x}\right] \cdot \frac{1}{E[X]} \ge 0$$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Chebyshev's Inequality

- X is a non-negative random variable with $E[x] = \mu$ and $Var(x) = \sigma^2$
- for any k > 0

$$P(|X - \mu| \ge k) \le \frac{\sigma^2}{k^2}$$

Proof

we know that

$$(X-\mu)^2 \ge 0$$

therefore, applying Markov's inequality

$$P\left((X-\mu)^2 \ge k^2\right) \le \frac{E\left[(X-\mu)^2\right]}{k^2} = \frac{\sigma^2}{k^2}$$

but since $(X - \mu)^2 \ge k^2 \rightarrow |X - \mu| \ge k$, Chebyshev's inequality follows

Chebyshev's Inequality implications

• if $k = r\sigma$

$$P(|X - \mu| \ge r\sigma) \le \frac{\sigma^2}{r^2\sigma^2} = \frac{1}{r^2}$$

- meaning that the probability that X deviates from its expected value at least r standard deviations is less than 1/r²
- as an example

$$P(|X - \mu| \ge 2\sigma) \le 1/4 = 25\%$$

 $P(|X - \mu| \ge 4\sigma) \le 1/16 = 6.25\%$
 $P(|X - \mu| \ge 10\sigma) \le 1/100 = 1\%$

since

$$1 - P(|X - \mu| < r\sigma) = P(|X - \mu| \ge r\sigma) \le \frac{1}{r^2}$$

• it follows that

$$P(|X - \mu| < r\sigma) \ge 1 - \frac{1}{r^2}$$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

22

Chebyshev's Inequality application

Exercise

- the same a post office handles, on average, 10⁴ letters per day, with a variance of 2000 letters
- (a) what is the probability it will handle between 8000 and 12000 letters, tomorrow?

Solution

- we know that $E[X] = 10^4$ and $\sigma^2 = Var(X) = 2 \cdot 10^3$
- we need to evaluate

$$P(8 \cdot 10^{3} < X < 12 \cdot 10^{3}) = P(|X - 10^{4}| < 2 \cdot 10^{3})$$

= $1 - P(|X - 10^{4}| \ge 2 \cdot 10^{3})$

- since $k\sigma = 2000 \rightarrow k = 2000/\sigma = 2000/\sqrt{2000}$
- therefore

$$P(|X - 10^4| \ge 2 \cdot 10^3) = 1 - P(8 \cdot 10^3 < X < 12 \cdot 10^3) \ge \frac{2 \cdot 10^3}{(2 \cdot 10^3)^2} = 5 \cdot 10^{-4}$$

and

$$P(8 \cdot 10^3 < X < 12 \cdot 10^3) \ge 1 - 5 \cdot 10^{-4} = 0.9995$$

A. Garfagnini (UniPD)

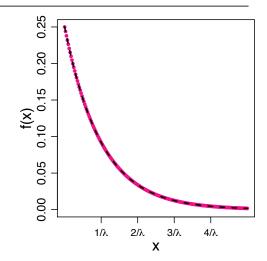

Exponential Random Variables

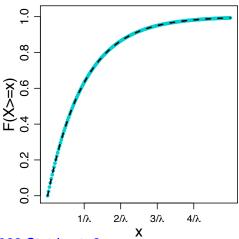

- consider a Poisson process {N(t) : t ≥ 0} where N(t) represents the number of events that happened at or before time t:
- T₁ is the time of the first event
- T₂ is the time between the first and the second event
- T_j is the time between events j-1 and j
- this sequence, also called inter-arrival times follows an exponential distribution, $X \sim \text{Exp}(\lambda)$

$$f(x) = \lambda e^{-\lambda x}$$
 with $\lambda > 0$

$$E[X] = \frac{1}{\lambda}$$
 $Var(x) = \frac{1}{\lambda^2}$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

$Exp(\lambda)$ property: lack of memory

- important feature of the exponential distribution is the memory-less property
- a positive random variable X is called memory-less if $\forall s, t \geq 0$,

$$P(X > s + t \mid X > s) = P(X > t)$$

- --> suppose you are in front of an elevator
- \rightarrow and you have already waited for three minutes (s = 3)
- --> the probability to wait for another two minutes (t = 2) is the same as you just arrived in front of the same elevator
- ⇒ but this is only true for an exponential distribution

Proof

our requirements is

$$P(X > s + t \mid X > s) = \frac{P(X > s + t)}{P(X > s)}$$
$$= \frac{e^{-(s+t)/\lambda}}{e^{-s/\lambda}}$$
$$= e^{-t/\lambda} = P(X > t)$$

therefore our hypothesis follows: X is memory-less

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Exercise

Problem

- The lifetime of an electronic component, in years, is a random variable with mean 10 years
- I bought the component 5 years ago.
- What is the probability that it will last for another 10 years?

Solution

• 10 years is the expected lifetime of the component, therefore:

$$E[x] = 10 \text{ years} = \lambda^{-1}$$

our variable follows an exponential distribution → it is a memory-less process:

$$P(x > 15 \mid x > 10) = P(x > 5) = 1 - P(x \le 5)$$

```
lambda <- 1/10
x <- 5

# [1] 0.6065307</pre>
```

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Analogy between $\text{Exp}(\lambda)$ and Geo(p)

if a Bernoulli trial is performed successively and independently

- the number of trials until the first success occurs follows Geo(p)
- but also the number of trials between two consecutive successes follows Geo(p)

let's now consider a Poisson process

- the time it will take until the first event occurs is $Exp(\lambda)$
- the time between two consecutive events is also $Exp(\lambda)$
- moreover $\text{Exp}(\lambda)$ is the only memory-less continuous distribution, and Geo(p) is the only memory-less discrete distribution

The Erlang distribution

- let's consider again a Poisson process $\{N(t): t \ge 0\}$ where N(t) represents the number of events that happened at or before time t:
- being T_j the time between events j-1 and j, the sequence $\{T_1, T_2, ...\}$ distributes as $\text{Exp}(\lambda)$
- let now X be the time of the n-th event
- X follows a so-called Gamma distribution with parameters n and λ

$$f(x) = \frac{x^{n-1} \lambda^n e^{-\lambda x}}{(n-1)!}$$

- → Exponential is the time to wait for the first event to occur
- → Gamma is the time to wait for the *n*-th event to occur
 - an Erlang distribution with parameters $(1, \lambda)$ is an exponential distribution:

$$Gamma(1, \lambda) \sim Exp(\lambda)$$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

28

From Erlang to Gamma distributions

- we want to extend the parameters of the Erlang distribution from (n, λ) to (r, λ) , where r is a real and positive number
- the factorial (n-1)! can be extended using the Gamma function, $\Gamma:(0,\infty)\longmapsto\mathbb{R}$:

$$\Gamma(r) = \int_{0}^{\infty} x^{r-1} e^{-x} dx$$

• the function has the same property of the factorials:

$$n! = n \cdot (n-1)!$$

 $\Gamma(\alpha) = (\alpha - 1) \cdot \Gamma(\alpha - 1)$ with $\alpha > 1$

• if r is integer, we get back the factorials:

$$\Gamma(1) = \int_{0}^{\infty} e^{-x} dx = 1$$

and

$$\Gamma(2)$$
 = $(2-1)\Gamma(2-1) = 1 = 1!$
 $\Gamma(3)$ = $(3-1)\Gamma(3-1) = 2 \cdot 1 = 2!$
...
 $\Gamma(n+1)$ = $n!$

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

The Gamma distribution

• a random variable X follows a gamma distribution, $X \sim \text{Gamma}(\alpha, \lambda)$, if the pdf has the form

$$f(x) = \frac{1}{\Gamma(\alpha)} x^{\alpha-1} \lambda^{\alpha} e^{-\lambda x}$$
 with $x \ge 0$

- the parameters $\alpha > 0$ and $\lambda > 0$ are called shape and scale parameters, respectively
- \rightsquigarrow therefore, if $X \sim \text{Gamma}(\alpha, 1)$, then $X/\lambda \sim \text{Gamma}(\alpha, \lambda)$
 - the Gamma distribution is a generalization of the exponential density with a mode at some strictly positive m value
 - it includes the exponential as a special case and can be very skewed, to being almost a bell-shaped density
 - we will show that it arises, naturally, as the density of the sum of a number of independent exponential random variables
 - the CDF of the Gamma distribution does not exist in explicit form, therefore the inverse method cannot be used for variate generation
 - in Bayesian analysis is a natural conjugate prior for the standard deviation of a normal distribution

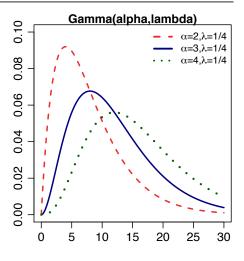

A. Garfagnini (UniPD)

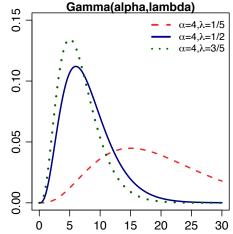

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

30

Gamma distribution in R

- keeping λ fixed, the maximum of the peak moves to the right with increasing values of α
- a similar behavior can be seen by keeping α fixed, and increasing λ to higher values

A. Garfagnini (UniPD)

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

Sum of variables with an exponential distribution

- let's suppose we have n independent variables $T_j \sim \text{Exp}(\lambda)$, with j = 1, ..., n
- we build $Y_n = \sum_{j=1}^n T_j$
- it can be proved that $Y_n \sim \text{Gamma}(n, \lambda)$

Proof

• T_i are all independent for $t < 1/\lambda$

$$E[\exp(Y_n t)] = E[\exp((T_1 + T_2 + ... T_n)t)]$$

$$= E[\exp(T_1 t) \exp(T_2 t) ... \exp(T_n t)]$$

$$= E[\exp(T_1 t)]E[\exp(T_2 t)] ... E[\exp(T_n t)]$$

$$= \prod_{j=1}^{n} (1 - \lambda t)^{-1}$$

$$= (1 - \lambda t)^{-n}$$

• therefore $Y_n \sim \text{Gamma}(n, \lambda)$

The Beta distribution

• a random variable X follows a beta distribution, $X \sim \text{Beta}(\alpha, \beta)$, if the pdf is

$$f(x) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha) \Gamma(\beta)} x^{\alpha - 1} (1 - x)^{\beta - 1} \text{ with } 0 \le x \le 1 \text{ and } \alpha, \beta > 0$$

- --> beta densities appear in the study of the median of a sample of random points $\sim \mathcal{U}\left(0,1\right)$
- ---> let's generate n points $X_j \sim \text{Beta}(\alpha, \beta)$ and assume they are ordered X_1, X_2, \dots, X_n with $X_{j+1} > X_j$
- \rightarrow if n = 2k + 1 (n is odd), the median is X_{k+1}
- \rightarrow if n = 2k (n is even), the median is $(X_k + X_{k+1})/2$
- \implies the median of 2n + 1 random numbers $\sim \mathcal{U}(0, 1)$ is $\sim \text{Beta}(n + 1, n + 1)$
 - the expected value and variance are

$$E[X] = \frac{\alpha}{\alpha + \beta}$$
 and $Var(x) = \frac{\alpha\beta}{(\alpha + \beta)^2(\alpha + \beta + 1)}$

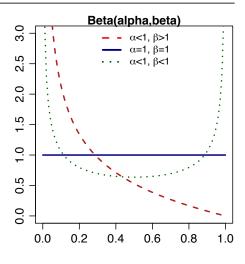

the central moments are

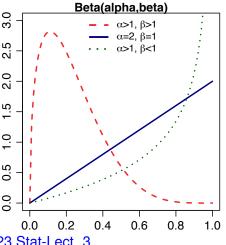

$$E[X^n] = \frac{\Gamma(\alpha + n)\Gamma(\alpha + \beta)}{\Gamma(\alpha + \beta + n)\Gamma(\alpha)}$$

A. Garfagnini (UniPD)

Beta distribution in R

- a beta distribution can be
- Arr increasing $\alpha > 1$ and $\beta < 1$
- \uparrow decreasing α < 1 and β > 1
- Arr symmetric unimodal $\alpha = \beta$
- Arr asymmetric unimodal $\alpha \neq \beta$
- Arr U-shaped α < 1 and β < 1
- it cannot be bimodal: it cannot have two local maxima in the interval [0, 1]
- note that Beta(1,1) is simply $\mathcal{U}(0,1)$

AdvStat 4 PhysAna - AA 2022-2023 Stat-Lect. 3

A. Garfagnini (UniPD)

Example: mixture of Beta distributions

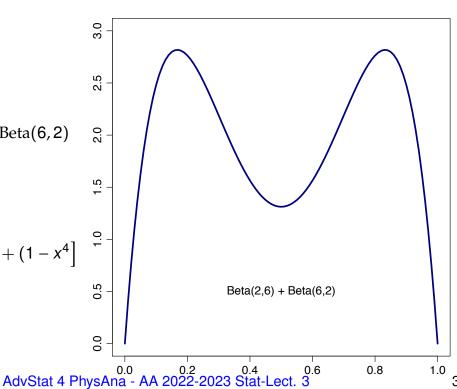

- a beta distribution can have only one mode in [0,1]
- in some cases we have to model a random variable that exhibit two modes, for some physical reason
- this can be done by mixing two beta distributions

$$f(x) = \frac{1}{2} \text{Beta}(2,6) + \frac{1}{2} \text{Beta}(6,2)$$

$$= \frac{1}{2} \left[42x^5 (1-x) \right]$$

$$+ \frac{1}{2} \left[42x (1-x)^5 \right]$$

$$= 21 \ x \ (1-x) \left[x^4 + (1-x^4) \right]$$

35

• a random variable X follows a normal distribution, $X \sim N(\mu, \sigma^2)$, if the pdf is

$$f(x) = \frac{1}{\sigma \sqrt{2 \pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

- --> where μ can be any real number and σ > 0 and teh distribution is called standard normal
- if $\mu = 0$ and $\sigma = 1$, it is called a standard normal distribution $X \sim N(0, 1)$
- the expected value and variance are

$$E[X] = \mu$$
 and $Var(x) = \sigma^2$

A. Garfagnini (UniPD)

The sum of independent normal variables

- ullet the standard normal distribution is symmetric and unimodal about the mean, μ
- keeping σ^2 fixed, and changeing μ the normal distribution only gets shifted to a new center
- mantaining μ fixed and increasing σ^2 , the distribution becomes more spread out about the same mean value

Theorem

- let $X_1, X_2, ..., X_n$, independent random variables with $X_j \sim N(\mu_j, \sigma_j^2)$
- we build $Y_n = \sum_{j=1}^n X_j$
- it can be proved that

$$Y_n \sim \text{Norm}\left(\sum_{j=1}^n \mu_j, \sum_{j=1}^n \sigma_j^2\right)$$

Still on the sum of independent normal variables

Corollary

- given *n* random variables, all following the same $N(\mu, \sigma^2)$ distribution
- then

$$\overline{X} = \frac{\sum X_j}{n} \sim \text{Norm}\left(\mu, \frac{\sigma^2}{n}\right)$$

 \Rightarrow the distribution of X gets more concentrated around the mean value μ as n increases, because the variance, σ^2 , decreases with n

Theorem

any linear combination of independent normal variables is also normal

$$\sum_{j=1}^{n} a_j X_j \sim \text{Norm}\left(\sum_{j=1}^{n} a_j \mu_j, \sum_{j=1}^{n} a_j^2 \sigma_j^2\right)$$

38

Limit Theorems

- let $X_1, X_2, ..., X_n$ independent random variables from the same distribution with mean μ and variance σ^2
- we define $S_n = \sum_{j=1}^n X_j$
- since X_j are independent and identically distributed,

$$E[S_n] = nE[X_i] = n\mu$$
 and $Var(S_n) = nVar(X_i) = n\sigma^2$

• the following theorems apply

Strong Law of Large Numbers

$$P\left(\lim_{n\to\infty}\frac{S_n}{n}=\mu\right)=1$$

Central Limit Theorem

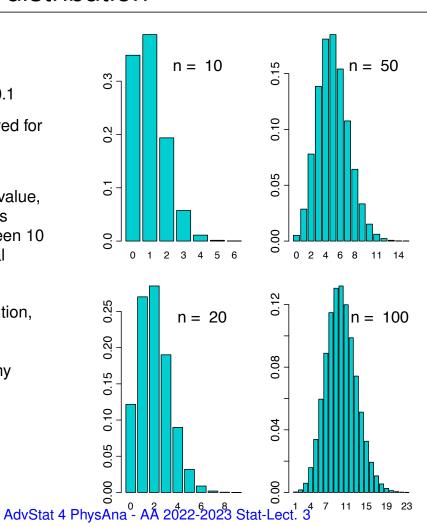

$$\lim_{n\to\infty} P\left(\frac{S_n - n\mu}{\sigma\sqrt{n}} \le x\right) = \Phi(x)$$

Where $\Phi(x)$ is the CDF of the standard normal distribution

A. Garfagnini (UniPD)

CLT for Binomial distribution

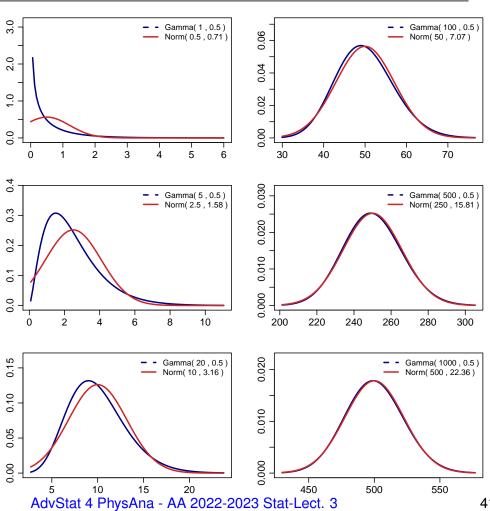

- $X \sim \text{Binom}(n, p)$ with p = 0.1
- the histogram is rather skewed for the small n values
- as n increases, it gets less skewed, and for the largest value, n = 100, the histogram looks bell-shaped, centered between 10 and 11, resembling a normal density curve
- indeed, the binomial distribution, Binom(n, p) can be well approximated by Norm (np, np(1-p)), for any fixed p, when n is large

A. Garfagnini (UniPD)

CLT for Gamma distribution

- the sum of variables distributed according to Gamma(α , λ) is again a gamma distribution
- the CLT tell us that when the number of terms in the sum is large, the resulting gamma distribution should be approximately normal
- the larger alpha, the less skewed the distribution of the individual terms is \rightarrow the smaller *n* has to be to get a good normal approximation
